

1. The Map/Dictionary abstract data type (ADT) stores key-value pairs. The key is used to look up the data value.

Method call	Class Name	Description
<code>d = ListDict()</code>	<code>__init__(self)</code>	Constructs an empty dictionary
<code>d["Name"] = "Bob"</code>	<code>__setitem__(self, key, value)</code>	Inserts a key-value entry if key does not exist or replaces the old value with value if key exists.
<code>temp = d["Name"]</code>	<code>__getitem__(self, key)</code>	Given a key return its value or None if key is not in the dictionary
<code>del d["Name"]</code>	<code>__delitem__(self, key)</code>	Removes the entry associated with key
<code>if "Name" in d:</code>	<code>__contains__(self, key)</code>	Return True if key is in the dictionary; return False otherwise
<code>for k in d:</code>	<code>__iter__(self)</code>	Iterates over the keys in the dictionary
<code>len(d)</code>	<code>__len__(self)</code>	Returns the number of items in the dictionary
<code>str(d)</code>	<code>__str__(self)</code>	Returns a string representation of the dictionary

    def __iter__(self):
        """Iterates over the keys of the dictionary"""

```

for slotList in self._table:
 for entry in slotList:
 yield entry.getKey()
 raise StopIteration

Average
 $O(1)$
 worst
 $O(n)$

a) In `__getitem__`, why is the `entry = Entry(key, None)` object created?

So we have an Entry object with the target key for comparing with Entry objects already in the dictionary.

b) In `__getitem__`, where does `self._index` receive its value?

The "if key in self:" calls `__contains__` method that sets the `self._index` value

c) What single modification was needed to the UnorderedList's remove method?

Removes and returns now it just removed before

d) Complete the `__iter__` method.

1. The Dictionary implementation using open-address hashing was the OpenAddrHashDict class in lab7.zip.

```

from entry import Entry

class OpenAddrHashDict(object):
    EMPTY = None # class variables shared by all objects of the class
    DELETED = True

    def __init__(self, capacity = 8, hashFunction = hash,
                 linear = True):
        self._table = [OpenAddrHashDict.EMPTY] * capacity
        self._size = 0
        self._hash = hashFunction
        self._homeIndex = -1
        self._actualIndex = -1
        self._linear = linear
        self._probeCount = 0

    def __getitem__(self, key):
        """Returns the value associated with key or
        returns None if key does not exist."""
        if key in self:
            return self._table[self._actualIndex].getValue()
        else:
            return None

    def __delitem__(self, key):
        """Removes the entry associated with key."""
