Question 1. (4 points) Consider the following Python code.

```python
for i in range(n):
    for j in range(n * n):
        for k in range(n):
            print( i, j, k )
```

What is the big-oh notation $O(\ )$ for this code segment in terms of $n$?

Question 2. (4 points) Consider the following Python code.

```python
i = 1
while i < n:
    for j in range(n):
        print(i, j)
    for k in range(n):
        print(i, k)
    i = i * 2
```

What is the big-oh notation $O(\ )$ for this code segment in terms of $n$?

Question 3. (4 points) Consider the following Python code.

```python
def main(n):
    for i in range(n):
        doSomething(n)

def doSomething(n):
    for k in range(n):
        doMore(n)
        print(k)

def doMore(n):
    for j in range(n):
        print(j)
```

```python
main(n)
```

What is the big-oh notation $O(\ )$ for this code segment in terms of $n$?

Question 4. (8 points) Suppose a $O( n^3 )$ algorithm takes 1 second when $n = 1000$. How long would the algorithm run when $n = 10,000$?

Question 5. (10 points) Why should a method/function having a "precondition" raise an exception if the precondition is violated?
Question 6. A Deque (pronounced “Deck”) is a linear data structure which behaves like a double-ended queue, i.e., it allows adding or removing items from either the front or the rear of the Deque. One possible implementation of a Deque would be to use a built-in Python list to store the Deque items such that
- the front item is always stored at index 0,
- the rear item is always at index len(self._items)-1 or -1

![Deque Object](image)

Python List Object

<table>
<thead>
<tr>
<th>_items:</th>
<th>Python List Object</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ 'a', 'b', 'c', 'd' ]</td>
<td>0 1 2 3</td>
</tr>
<tr>
<td>front</td>
<td>rear</td>
</tr>
</tbody>
</table>

### a) (6 points)
Complete the big-oh $O(\_)$, for each Deque operation, assuming the above implementation. Let $n$ be the number of items in the Deque.

<table>
<thead>
<tr>
<th>Operation</th>
<th>Big-oh</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>isEmpty</code></td>
<td>$O(1)$</td>
</tr>
<tr>
<td><code>addRear</code></td>
<td>$O(1)$</td>
</tr>
<tr>
<td><code>removeRear</code></td>
<td>$O(1)$</td>
</tr>
<tr>
<td><code>addFront</code></td>
<td>$O(1)$</td>
</tr>
<tr>
<td><code>removeFront</code></td>
<td>$O(1)$</td>
</tr>
<tr>
<td><code>__str__</code></td>
<td>$O(n)$</td>
</tr>
</tbody>
</table>

### b) (7 points)
Complete the method for the `removeFront` operation including the precondition check.

```python
def removeFront(self):
    """Removes and returns the front item of the Deque
    Precondition: the Deque is not empty.
    Postcondition: Front item is removed and returned from the Deque"
    return self._items.pop(0)
```

### c) (7 points)
Complete the method for the `__str__` operation.

```python
def __str__(self):
    """Returns the string representation of the Deque.
    Precondition: none
    Postcondition: Returns a string representation of the Deque from the
    front item thru the rear item with a blank space between each item."""

    resultStr = ""
    return resultStr
```
Question 7. Consider the binary heap approach to implement a priority queue. A Python list is used to store a complete binary tree (a full tree with any additional leaves as far left as possible) with the items being arranged by heap-order property, i.e., each node is $\leq$ either of its children. An example of a min heap “viewed” as a complete binary tree would be:

```
   8
  / \
 12  15
 /   /
35   30
 /   /
54   56
```

Python List actually used to store heap items
```
[8] [12] [15] [35] [24] [40] [30] [100] [54] [37] [32] [56]
```

a) (3 points) For the above heap, the list indexes are indicated in [ ]'s. For a node at index $i$, what is the index of:

- its left child if it exists:
- its right child if it exists:
- its parent if it exists:

b) (7 points) What would the above heap look like after inserting 13 and then 10 (show the changes on above tree)

Now consider the delMin operation that removes and returns the minimum item.

```
   8
  / \
 12  15
 /   /
35   30
 /   /
54   56
```

c) (2 point) What item would delMin remove and return from the above heap?

d) (7 points) What would the above heap look like after a delMin operation? (show the changes on above tree)

e) (6 points) Explain why both of the insert and delMin operations are $O(\log_2 n)$, where $n$ is the number of items in the heap.
Question 8. The Node class can be used to dynamically create storage for each new item added to a Deque using a singly-linked implementation as in:

```
LinkedDeque Object          Node Objects
  _size: 4
  _front: None
  _rear: None
    data   next  data   next  data   next  data   next
       'd'    —    'c'    —    'b'    —    'a'

a) (6 points) Complete the big-oh $O()$, for each LinkedDeque operation, assuming the above implementation. Let $n$ be the number of items in the LinkedDeque.

<table>
<thead>
<tr>
<th>isEmpty</th>
<th>addRear</th>
<th>removeRear</th>
<th>addFront</th>
<th>removeFront</th>
<th><strong>str</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

b) (14 points) Complete the addFront method for the above LinkedDeque implementation.

```python
class LinkedDeque(object):
    """Singly-linked list based deque implementation."""
    def __init__(self):
        self._size = 0
        self._front = None
        self._rear = None
    def addFront(self, newItem):
        """Adds the newItem to the front of the Deque.
        Precondition: none """
```

c) (5 points) Would using doubly-linked nodes (Node2Way with previous, data, and next) improvement the above implementation (i.e., speed up some of the queue operations enough to change their big-oh notation)? Justify your answer.
