## Data Structures (CS 1520)

## Lecture 8

Name:	
ranic.	

1. The textbook's unordered list ADT uses a singly-linked list implementation. I added the \_size and \_tail attributes:

a) The search(targetItem) method searches for targetItem in the list. It returns True if targetItem is in the list; otherwise it returns False. Complete the search(targetItem) method code:

```
class UnsortedList:
def search(self, targetItem):
```

b) The textbook's unordered list ADT does not allow duplicate items, so operations <code>add(item)</code>, <code>append(item)</code>, and <code>insert(pos, item)</code> would have what precondition?

c) Complete the append(item) method including a check of it's precondition(s)?

```
def append(self, item):
```

d) Why do you suppose I added a  $\_tail$  attribute?

e) The textbook's remove(item) and index(item) operations "Assume the item is present in the list." Thus, they would have a precondition like "Item is in the list." When writing a program using an UnorderedList object (say myGroceryList = UnorderedList()), how would the programmer check if the precondition is satisfied?

 $\verb|itemToRemove| = \verb|input("Enter the item to remove from the Grocery list: ")|\\$ 

if

myGroceryList.remove(itemToRemove)

Data Structures (CS 1520)	Lecture 8	Name:
<pre>f) The remove(item) and index(item) process?</pre>	methods both need to look for the item.	What is inefficient in this whole
g) Modify the search(targetItem) meth the remove(item) and index(item) meth		ributes to aid the implementation of
h) Write the $index(item)$ method include	ing a check of its precondition(s).	
<pre>def index(self, item):</pre>		
i) Write the remove(item) method include	ding a check of its precondition(s).	
<pre>def remove(self, item):</pre>		
j) Write the pop(position) and pop() m	ethod including a check of its precondit	ion(s).
<pre>def pop(self, position = None)</pre>	:
