

2. More partial TreeNode class and partial BinarySearchTree class.

```

class BinarySearchTree:
    ...
    def delete(self, key):
        if self.size > 1:
            nodeToRemove = self._get(key, self.root)
            if nodeToRemove:
                self.remove(nodeToRemove)
                self.size = self.size - 1
            else:
                raise KeyError('Error, key not in tree')
        elif self.size == 1 and self.root.key == key:
            self.root = None
            self.size = self.size - 1
        else:
            raise KeyError('Error, key not in tree')

    def __delitem__(self, key):
        self.delete(key)

    def remove(self, currentNode):
        if currentNode.isLeaf(): #leaf
            if currentNode == currentNode.parent.leftChild:
                currentNode.parent.leftChild = None
            else:
                currentNode.parent.rightChild = None
        elif currentNode.hasBothChildren(): #interior
            succ = currentNode.findSuccessor()
            succ.spliceOut()
            currentNode.key = succ.key
            currentNode.payload = succ.payload

        else: # this node has one child
            if currentNode.hasLeftChild():
                if currentNode.isLeftChild():
                    currentNode.leftChild.parent = currentNode.parent
                    currentNode.parent.leftChild = currentNode.leftChild
                elif currentNode.isRightChild():
                    currentNode.leftChild.parent = currentNode.parent
                    currentNode.parent.rightChild = currentNode.leftChild
                else:
                    currentNode.replaceNodeData(currentNode.leftChild.key,
                                                currentNode.leftChild.payload,
                                                currentNode.leftChild.leftChild,
                                                currentNode.leftChild.rightChild)

            else:
                if currentNode.isLeftChild():
                    currentNode.rightChild.parent = currentNode.parent
                    currentNode.parent.leftChild = currentNode.rightChild
                elif currentNode.isRightChild():
                    currentNode.rightChild.parent = currentNode.parent
                    currentNode.parent.rightChild = currentNode.rightChild
                else:
                    currentNode.replaceNodeData(currentNode.rightChild.key,
                                                currentNode.rightChild.payload,
                                                currentNode.rightChild.leftChild,
                                                currentNode.rightChild.rightChild)

```

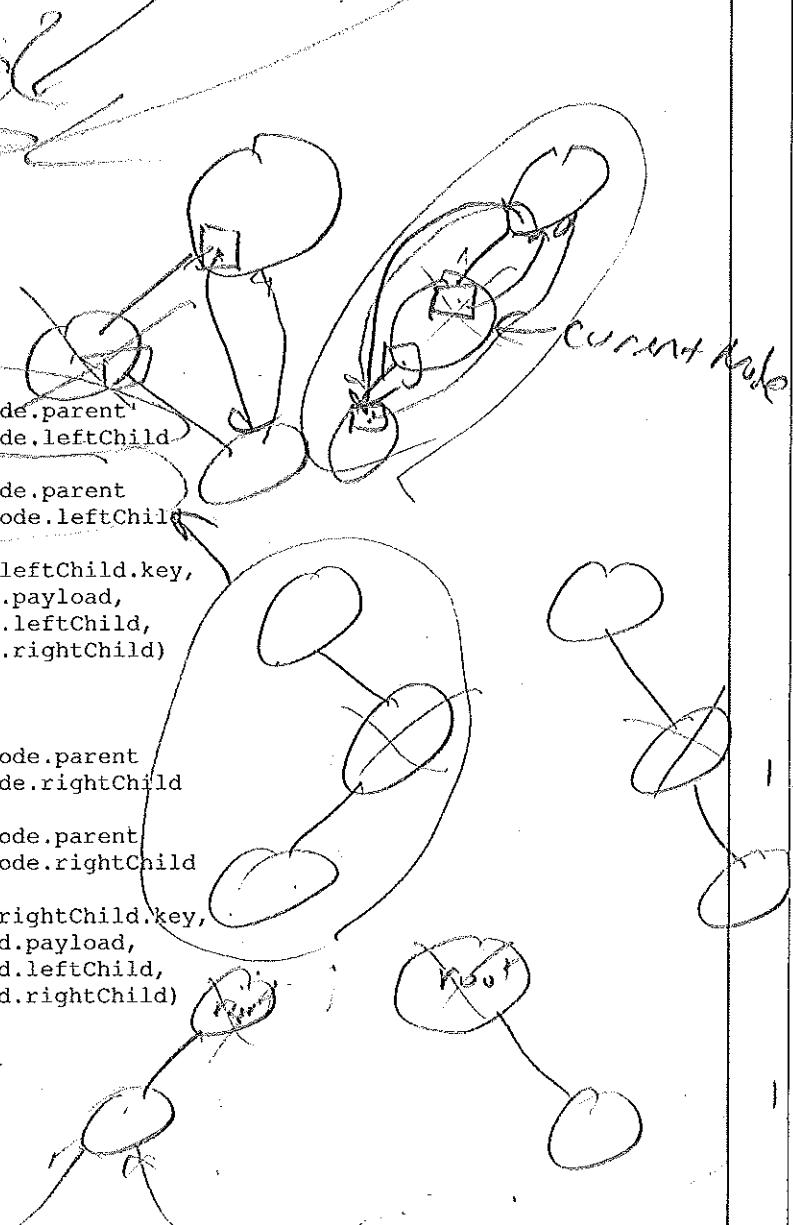

a) Update picture where we delete a leaf.

BinarySearchTree

b) Where in the code is each handled?

c) Draw all pictures deleting all nodes with one child.

3. Yet even more partial TreeNode class and partial BinarySearchTree class.

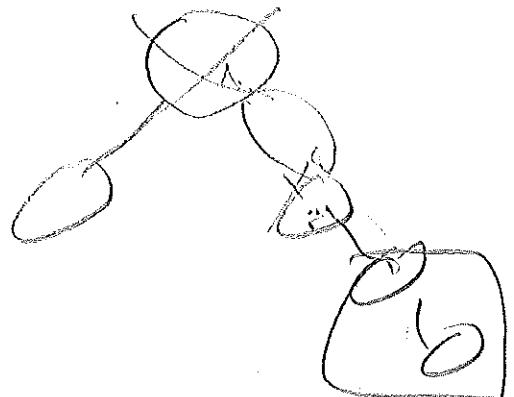

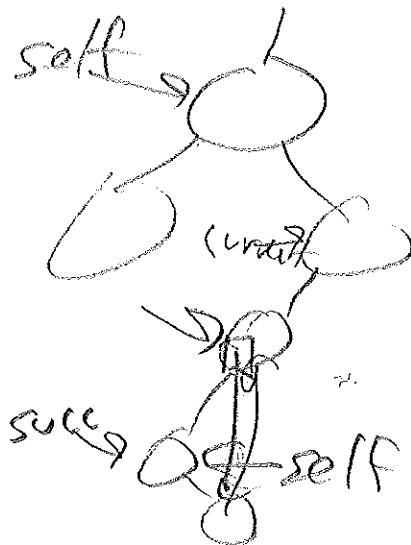

```

class TreeNode:
    ...
    def findSuccessor(self):
        succ = None
        if self.hasRightChild():
            succ = self.rightChild.findMin()
        else:
            if self.parent:
                if self.isLeftChild():
                    succ = self.parent
                else:
                    self.parent.rightChild = None
                    succ = self.parent.findSuccessor()
                    self.parent.rightChild = self
        return succ

    def findMin(self):
        current = self
        while current.hasLeftChild():
            current = current.leftChild
        return current

    def spliceOut(self):
        if self.isLeaf():
            if self.isLeftChild():
                self.parent.leftChild = None
            else:
                self.parent.rightChild = None
        elif self.hasAnyChildren():
            if self.isLeftChild():
                if self.parent.leftChild == self:
                    self.parent.leftChild = self.leftChild
                else:
                    self.parent.rightChild = self.leftChild
                    self.leftChild.parent = self.parent
            else:
                if self.parent.rightChild == self:
                    self.parent.rightChild = self.rightChild
                else:
                    self.parent.leftChild = self.rightChild
                    self.rightChild.parent = self.parent

```

1. Consider the Binary Search Tree (BST):

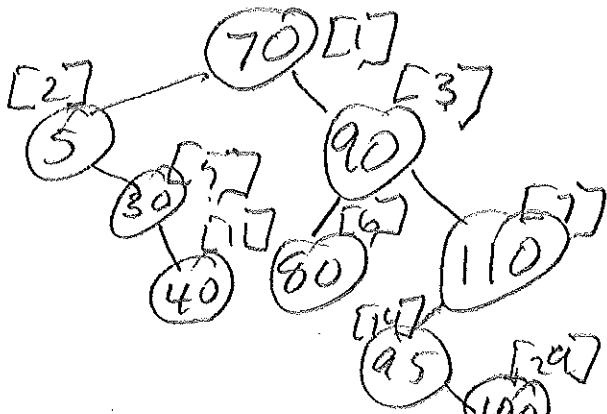

- a. What would need to be done to delete 32 from the BST? (1) Find it - search for it
- b. What would need to be done to delete 9 from the BST? Rewrite parent's child pointer to deleted node's child
- c. What would be the result of deleting 50 from the BST? Hint: One technique when programming is to convert a hard problem into a simpler problem. Deleting a BST node that contains two children is a hard problem. Since we know how to delete a BST node with none or one child, we can convert "deleting a node with two children" problem into a simpler problem by overwriting 50 with another node's value. Which nodes can be used to overwrite 50 and still maintain the BST ordering? 47 or 53
- d. Which node would the `TreeNode's findSuccessor` method return for `succ` if we are deleting 50 from the BST? 53
2. When the `findSuccessor` method is called how many children does the `self` node have? 2
3. How could we improve the `findSuccessor` method? - eliminate "dead" code that never runs (X'ed out)
4. When the `spliceOut` method is called from `remove` how many children could the `self` node have? at most a right child 1
5. How could we improve the `spliceOut` method? - eliminate "dead" code that never runs (X'ed out)

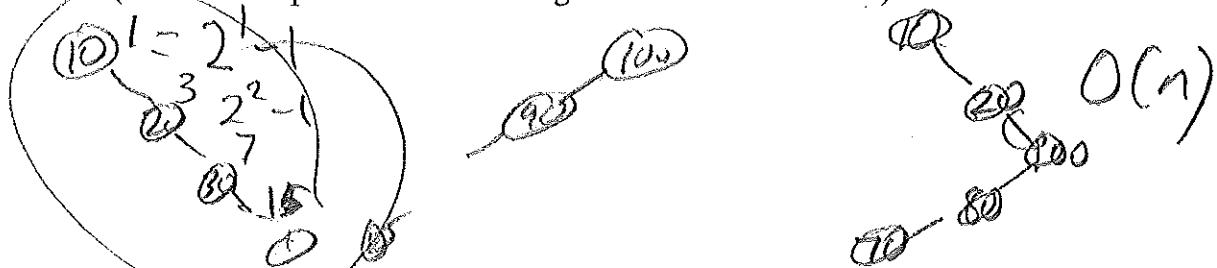

6. The shape of a BST depends on the order in which values are added (and deleted).

- a) What would be the shape of a BST if we start with an empty BST and insert the sequence of values:

70, 90, 80, 5, 30, 110, 95, 40, 100

- b) If a BST contains n nodes and we start searching at the root, what would be the worst-case big-oh $O()$ notation for a successful search? (Draw the shape of the BST leading to the worst-case search)

7. We could store a BST in an array like we did for a binary heap, e.g. root at index 1, node at index i having left child at index $2 * i$, and right child at index $2 * i + 1$.

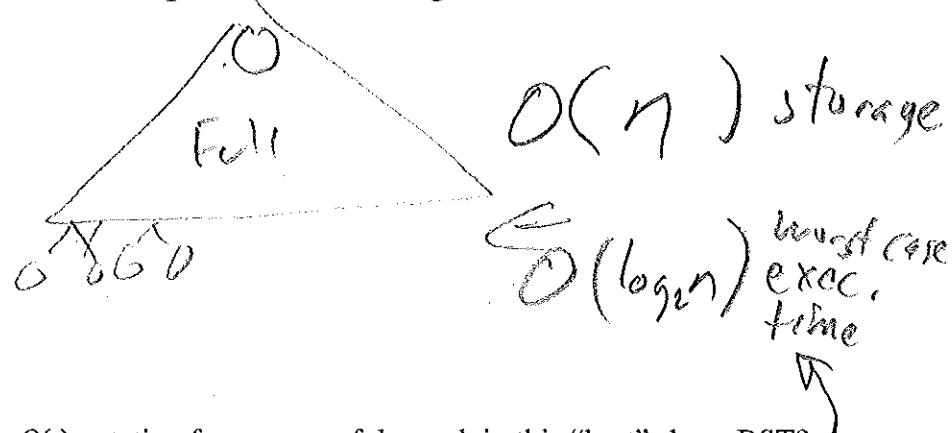

- a) Draw the above BST (after inserting: 70, 90, 80, 5, 30, 110, 95, 40, 100) stored in an array (leave blank unused slots)

0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31			
Index 0 Value 70	5	90		30	80	110			40		95																							

- b) What would be the worst-case storage needed for a BST with n nodes?

index $2^n - 1$ $O(2^n)$ storage
 $O(n)$ exec. time

8. a) If a BST contains n nodes, draw the shape of the BST leading to best, successful search in the worst case.

- b) What is the worst-case big-oh $O()$ notation for a successful search in this "best" shape BST?
