Objectives: To understand how a graph can be represented and traversed.

To start the lab: Download and unzip the file http://www.cs.uni.edu/~fienup/cs1520s17/labs/lab11.zip

Part A: In a word-ladder puzzle (discussed in class) transforms one word into another by changing one letter at a time, e.g., transform FOOL into SAGE by FOOL → FOIL → FAIL → FALL → PALL → PALE → SALE → SAGE.
We used a graph algorithm to solve this problem by constructing a graph such that
- words are represented by the vertices, and
- edges connect vertices containing words that differ by only one letter

a) For the words listed below, complete the graph by adding edges as defined above.

b) To find the shortest transformation from FOOL to SAGE, why did we decide on using a Breadth First Search (BFS) traversal (i.e., where you find all vertices a distance 1 (directly connected) from FOOL, before finding all vertices a distance 2 from FOOL, etc) instead of a Depth-First Search (DFS) traversal?

c) Run the lab11/word_ladder_BFS.py program. Examine the “enqueue” and “dequeue” lines of output produced by the bfs(g, g.getVertex("fool")) call. Does this output match the expected “enqueues” and “dequeues” performed during a bfs of the above graph starting at “fool”?

d) The bfs algorithm sets the value of each vertex’s predecessor to point to the vertex object that enqueued it. Add code to the end of the word_ladder_BFS.py program that traverses the “linked list” of predecessor references from “sage” to “fool.” and prints the corresponding word ladder from “fool” to “sage.”

After you have answered the above questions and completed the code, raise your hand and explain your answers.
Part B: Section 7.5 uses recursion and the run-time stack to implement a DFS traversal. The `DFSGraph` uses a `time` attribute to note when a vertex if first encountered (discovery attribute) in the depth-first search and when a vertex in backtracked through (finish attribute). Consider the graph for making pancakes where vertices are steps and edges represents the partial order among the steps.

```python
class DFSGraph(Graph):
    def __init__(self):
        super().__init__()
        self.time = 0

def dfs(self):
    for aVertex in self:
        aVertex.setColor('white')
        aVertex.setPred(-1)
    for aVertex in self:
        if aVertex.getColor() == 'white':
            self.dfsvisit(aVertex)

    def dfsvisit(self,startVertex):
        startVertex.setColor('gray')
        self.time += 1
        startVertex.setDiscovery(self.time)
        for nextVertex in startVertex.getConnections():
            if nextVertex.getColor() == 'white':
                nextVertex.setPred(startVertex)
                self.dfsvisit(nextVertex)
        startVertex.setColor('black')
        self.time += 1
        startVertex.setFinish(self.time)
```

a) Run the `lab11/make_pancake_DFS.py` program. Write on the above graph the discovery and finish attributes (e.g., 1/12 of "oil") assigned to each vertex by executing the `dfs` method.

b) A topological sort algorithm can use the `dfs` finish attributes to determine a proper order to avoid putting the "cart before the horse." For example, we don't want to "pour ½ cup of batter" before we "mix the batter", and we don't want to "mix the batter" until all the ingredients have been added. Outline the steps to perform a topological sort from the finish attributes.

After you have answered the above questions, raise your hand and explain your answers.

**EXTRA CREDIT:**
Add code to the end of the `made_pancake_DFS.py` program to print the topological sort for making pancakes.
