

$$\begin{aligned}(1, 1) &= a \\ (1, 7) &= b \\ (5, 2) &= c \\ (5, 4) &= d\end{aligned}$$

03/10/2015

What is best fitting LINEAR equation
for the 4 points? LINEAR = line

$$y = mx + b$$

slope intercept

What would be good estimate for the
slope m ?

The line would need to go above a
and below b - and go between
points c and d too, right?

What is above $(1, 1)$ and below $(1, 7)$?
The midpoint would be $(1, \frac{1+7}{2})$ or $(1, \frac{8}{2})$
or $(1, 4)$

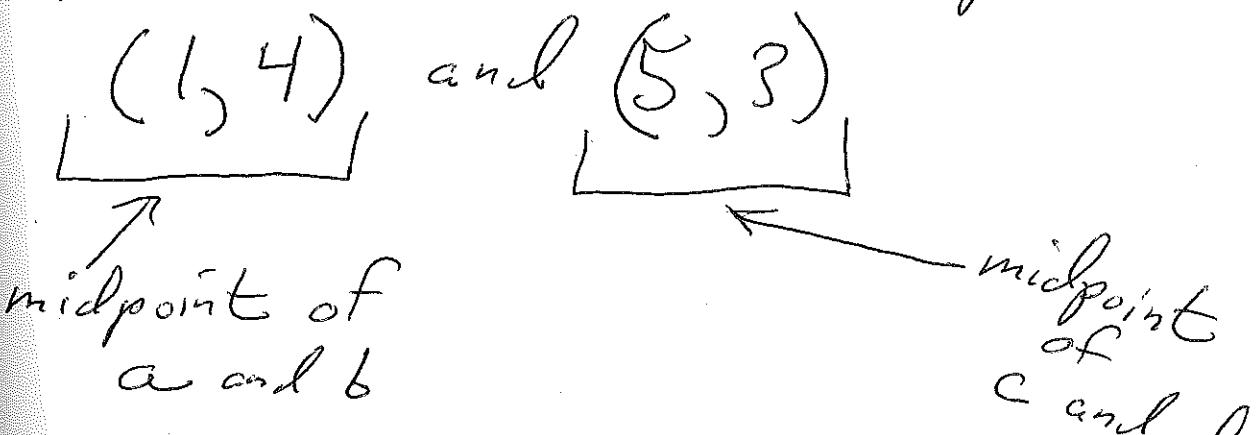

Slope = $\frac{\text{vertical change}}{\text{horizontal change}} = \frac{\text{rise}}{\text{run}} = \frac{\Delta y}{\Delta x}$

What is the midpoint that is exactly halfway between c and d, ie between $(5, 2)$ and $(5, 4)$?

It would be $(5, \frac{2+4}{2}) = (5, \frac{6}{2}) = (5, 3)$

So the slope of a line that best fits these 4 points a, b, c, and d would be:

Slope of line through two points

$$\text{Slope} = m = \frac{y_2 - y_1}{x_2 - x_1} = \frac{3 - 4}{5 - 1} = \frac{-1}{4}$$

* Slope formula: slope = $\frac{y_2 - y_1}{x_2 - x_1}$ = -0.25

$$y = -0.25x + b$$

slope *intercept* to be found using data files.

The slope here of -0.25 is perfect, and not just a guess or estimate that will get us close.

So the SHOOT Data Flyer program won't need to change the slope to improve the fit. It just needs to adjust the intercept, the b in $y = mx + b$.

- Slope = $\frac{\text{vertical change}}{\text{horizontal change}} = \frac{\text{output change}}{\text{input change}} = \frac{\text{rise}}{\text{run}} = \frac{\Delta y}{\Delta x}$
- Slope formula: slope = $\frac{y_2 - y_1}{x_2 - x_1}$
